#### Week 12

Chapter 11 Regression 11.1 Least squares estimation

# Regression

- Analysis of relations between random variables
- Regression of Y on  $X^{(1)}, ..., X^{(k)}$  is the conditional expectation:
  - $-\mathbf{E}(Y|X^{(1)}=x^{(1)},...,X^{(k)}=x^{(k)})$
  - *Y* is called the *response* or *dependent* variable. It is the variable we want to predict
  - $X^{(i)}$ s are called the *predictors* or *independent* variables.
- Linear multi-variate regression

$$-Y = \beta_0 + \beta_1 X^{(1)} + \beta_2 X^{(2)} + \dots + \beta_k X^{(k)}$$

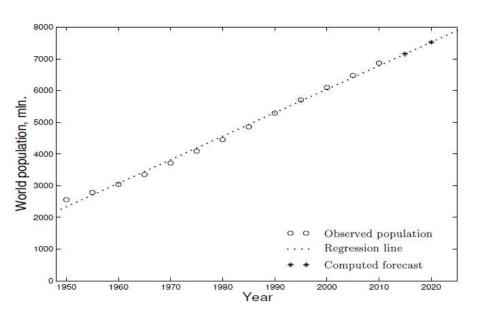

### Regression

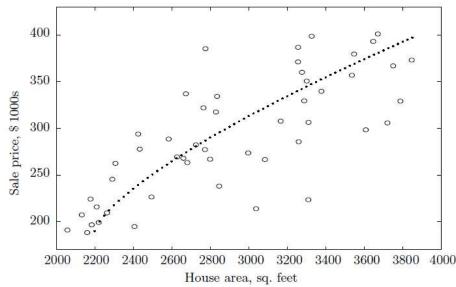

- In this course, we will cover the simplest form:
  - Univariate, linear regression

$$-G(x) = \mathbf{E}(Y|X = x) = \beta_0 + \beta_1 X$$

- Intercept:  $\beta_0 = G(0)$
- Slope:  $\beta_1 = G(x + 1) G(x)$

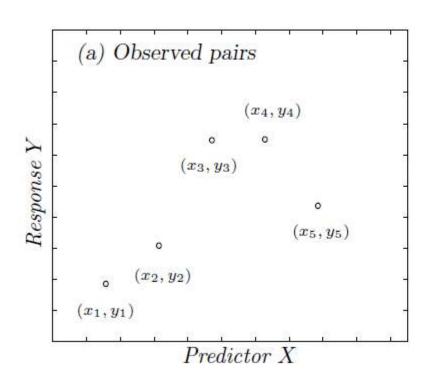

## Linear versus Non-Linear Regression

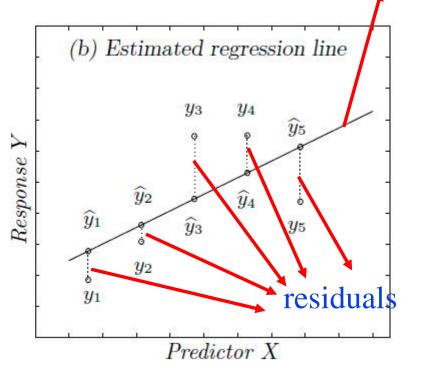

• Estimate the function G(x) with  $\hat{G}(x)$ 

-  $\widehat{G}(x)$ : try to minimize the distance between real observations and predictions

 $\widehat{G}(x)$ 

• Find  $\hat{G}(x)$  that minimizes the sum of squares of the residuals

$$-e_i = y_i - \hat{y}_i$$

- Minimize 
$$\sum_{i=1}^{n} e_i^2 = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

• 
$$Q = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 = \sum_{i=1}^{n} (y_i - \hat{G}(x_i))^2$$
  
=  $\sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i)^2$ 

• Take partial derivatives wrt  $\beta_0$  and  $\beta_1$  and equate to 0

normal equations 
$$\begin{cases} \sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i) = 0 \\ \sum_{i=1}^{n} x_i (y_i - \beta_0 - \beta_1 x_i) = 0 \end{cases}$$

• 
$$\sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i) = 0$$

$$\Rightarrow \beta_0 = \frac{\sum y_i - \beta_1 \sum x_i}{n} = \bar{y} - \beta_1 \bar{x}$$

• Substitute  $\beta_0$  in the second normal equation:

$$\rightarrow S_{xy} - \beta_1 S_{xx} = 0$$
 where

sum of squares 
$$S_{xx} = \sum_{i=1}^{n} (x_i - \bar{x})^2$$

sum of cross products 
$$S_{xy} = \sum_{i=1}^{n} (x_i - \bar{x})(y_i - \bar{y})$$

## Method of least squares steps

1. Compute  $\bar{x}$  and  $\bar{y}$ 

2. 
$$S_{xx} = \sum_{i=1}^{n} (x_i - \bar{x})^2$$

3. 
$$S_{xy} = \sum_{i=1}^{n} (x_i - \bar{x})(y_i - \bar{y})$$

4. 
$$b_1 = \hat{\beta}_1 = S_{xy}/S_{xx}$$

5. 
$$b_0 = \hat{\beta}_0 = \bar{y} - b_1 \bar{x}$$

• Example 11.3 (World Population)

#### Regression and correlation

• Recall that covariance and correlation coefficient are:

$$-Cov(X,Y) = E\left((X - E(X))(Y - E(Y))\right)$$
$$-\rho = \frac{Cov(X,Y)}{\sigma_X\sigma_Y}$$

• Sample covariance and sample correlation coefficient can be used to estimate Cov(X, Y) and  $\rho$ 

# Sample covariance and correlation coefficent

• 
$$s_{xy} = \frac{\sum_{i=1}^{n} (x_i - \bar{x})(y_i - \bar{y})}{n-1}$$

$$r = \frac{s_{xy}}{s_x s_y}$$

•  $s_x$  and  $s_y$  are sample standard deviations

• 
$$s_x = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n-1}}$$
 and  $s_y = \sqrt{\frac{\sum_{i=1}^n (y_i - \bar{y})^2}{n-1}}$ 

$$\Rightarrow b_1 = \frac{S_{xy}}{S_{xx}} = \frac{S_{xy}}{S_{x}S_{x}} = r\left(\frac{S_y}{S_x}\right)$$

# Why linear when we can have 0 sum of errors?

Answer: to avoid overfitting
